Chapter 7: Deadlocks
Chapter 7: Deadlocks

- The Deadlock Problem
- System Model
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock
Chapter Objectives

- To develop a description of deadlocks, which prevent sets of concurrent processes from completing their tasks
- To present a number of different methods for preventing or avoiding deadlocks in a computer system
The Deadlock Problem

- A set of blocked processes each holding a resource and waiting to acquire a resource held by another process in the set

- Example
  - System has 2 disk drives
  - \( P_1 \) and \( P_2 \) each hold one disk drive and each needs another one

- Example semaphores \( A \) and \( B \), initialized to 1

\[
\begin{align*}
  & P_0 & P_1 \\
  & \text{wait (A);} & \text{wait(B)}; \\
  \end{align*}
\]

\( \text{wait (A);} \)
Bridge Crossing Example

- Traffic only in one direction
- Each section of a bridge can be viewed as a resource
- If a deadlock occurs, it can be resolved if one car backs up (preempt resources and rollback)
- Several cars may have to be backed up if a deadlock occurs
- Starvation is possible
- Note – Most OSes do not prevent or deal with deadlocks
System Model

- Resource types $R_1, R_2, \ldots, R_m$
  
  *CPU cycles, memory space, I/O devices*

- Each resource type $R_i$ has $W_i$ instances

- Each process utilizes a resource as follows:
  
  - request
  - use
  - release
Deadlock Characterization

Deadlock can arise if four conditions hold simultaneously.

- **Mutual exclusion**: only one process at a time can use a resource

- **Hold and wait**: a process holding at least one resource is waiting to acquire additional resources held by other processes

- **No preemption**: a resource can be released only voluntarily by the process holding it, after that process has completed its task

- **Circular wait**: there exists a set \( \{P_0, P_1, \ldots, P_n\} \) of waiting processes such that \( P_0 \) is waiting for a resource that is held by \( P_1 \), \( P_1 \) is waiting for a resource that is held by \( P_2, \ldots, P_{n-1} \) is waiting for a resource that is held by \( P_n \), and \( P_n \) is waiting for a resource that is held by \( P_0 \)
Resource-Allocation Graph

A set of vertices $V$ and a set of edges $E$

- $V$ is partitioned into two types:
  - $P = \{P_1, P_2, \ldots, P_n\}$, the set consisting of all the processes in the system
  - $R = \{R_1, R_2, \ldots, R_m\}$, the set consisting of all resource types in the system

- **request edge** – directed edge $P_i \rightarrow R_j$

- **assignment edge** – directed edge $R_j \rightarrow P_i$
Resource-Allocation Graph (Cont.)

- Process

- Resource Type with 4 instances

- $P_i$ requests instance of $R_j$

- $P_i$ is holding an instance of $R_j$
Example of a Resource Allocation Graph
Resource Allocation Graph With A Deadlock
Graph With A Cycle But No Deadlock

- $P_1$ has a request for $R_2$.
- $P_2$ has a request for $R_1$.
- $P_3$ has a request for $R_2$.
- $P_4$ has a request for $R_2$.

There is a cycle in the graph ($P_1$ to $P_2$ to $P_3$ to $P_4$), but no deadlock since there are no circular wait sets.
Basic Facts

- If graph contains no cycles ⇒ no deadlock
- If graph contains a cycle ⇒
  - if only one instance per resource type, then deadlock
  - if several instances per resource type, possibility of deadlock
Java Deadlock Example

class A implements Runnable
{
    private Lock first, second;

    public A(Lock first, Lock second) {
        this.first = first;
        this.second = second;
    }

    public void run() {
        try {
            first.lock();
            // do something
            second.lock();
            // do something else
        }
        finally {
            first.unlock();
            second.unlock();
        }
    }
}

class B implements Runnable
{
    private Lock first, second;

    public A(Lock first, Lock second) {
        this.first = first;
        this.second = second;
    }

    public void run() {
        try {
            second.lock();
            // do something
            first.lock();
            // do something else
        }
        finally {
            second.unlock();
            first.unlock();
        }
    }
}
Java Deadlock Example

```java
public static void main(String arg[]) {
    Lock lockX = new ReentrantLock();
    Lock lockY = new ReentrantLock();

    Thread threadA = new Thread(new A(lockX, lockY));
    Thread threadB = new Thread(new B(lockX, lockY));

    threadA.start();
    threadB.start();
}
```

Deadlock is possible if:

threadA -> lockY -> threadB -> lockX -> threadA
public class ClockApplet extends Applet implements Runnable
{
    private Thread clockThread;
    private boolean ok = false;
    private Object mutex = new Object();

    public void run()
    {
        while (true) {
            try {
                // sleep for 1 second
                Thread.sleep(1000);

                // repaint the date and time
                repaint();

                // see if we need to suspend ourself
                synchronized (mutex) {
                    while (ok == false)
                        mutex.wait();
                }
            }
            catch (InterruptedException e) { }
        }
    }

    public void start()
    {
        // Figure 7.7
    }

    public void stop()
    {
        // Figure 7.7
    }

    public void paint(Graphics g){
        g.drawString(new java.util.Date().toString(),10,30);
    }
}
Handling Deadlocks in Java

```java
// this method is called when the applet is started or we return to the applet
public void start() {
    ok = true;

    if (clockThread == null) {
        clockThread = new Thread(this);
        clockThread.start();
    } else {
        synchronized(mutex) {
            mutex.notify();
        }
    }
}

// this method is called when we leave the page the applet is on
public void stop() {
    synchronized(mutex) {
        ok = false;
    }
}
```
Methods for Handling Deadlocks

- Ensure that the system will *never* enter a deadlock state
- Allow the system to enter a deadlock state and then recover
- Ignore the problem and pretend that deadlocks never occur in the system; used by most operating systems, including UNIX
Deadlock Prevention

Restrain the ways request can be made

- **Mutual Exclusion** – not required for sharable resources; must hold for non sharable resources

- **Hold and Wait** – must guarantee that whenever a process requests a resource, it does not hold any other resources
  - Require process to request and be allocated all its resources before it begins execution, or allow process to request resources only when the process has none
  - Low resource utilization; starvation possible
Deadlock Prevention (Cont.)

- **No Preemption** –
  - If a process that is holding some resources requests another resource that cannot be immediately allocated to it, then all resources currently being held are released.
  - Preempted resources are added to the list of resources for which the process is waiting.
  - Process will be restarted only when it can regain its old resources, as well as the new ones that it is requesting.

- **Circular Wait** – impose a total ordering of all resource types, and require that each process requests resources in an increasing order of enumeration.
Deadlock Avoidance

Requires that the system has some additional \textit{a priori} information available.

- Simplest and most useful model requires that each process declare the \textit{maximum number} of resources of each type that it may need.

- The deadlock-avoidance algorithm dynamically examines the resource-allocation state to ensure that there can never be a circular-wait condition.

- Resource-allocation \textit{state} is defined by the number of available and allocated resources, and the maximum demands of the processes.
Safe State

- When a process requests an available resource, the system must decide if immediate allocation leaves the system in a safe state.

- System is in **safe state** if there exists a sequence \(<P_1, P_2, \ldots, P_n>\) of ALL the processes is the systems such that for each \(P_i\), the resources that \(P_i\) can still request can be satisfied by currently available resources + resources held by all the \(P_j\), with \(j < i\).

- That is:
  - If \(P_i\) resource needs are not immediately available, then \(P_i\) can wait until all \(P_j\) have finished.
  - When \(P_j\) is finished, \(P_i\) can obtain needed resources, execute, return allocated resources, and terminate.
  - When \(P_i\) terminates, \(P_{i+1}\) can obtain its needed resources, and so on.
Basic Facts

- If a system is in safe state ⇒ no deadlocks
- If a system is in unsafe state ⇒ possibility of deadlock
- Avoidance ⇒ ensure that a system will never enter an unsafe state.
Safe, Unsafe, Deadlock State

- Deadlock
- Unsafe
- Safe
Avoidance algorithms

- Single instance of a resource type
  - Use a resource-allocation graph

- Multiple instances of a resource type
  - Use the banker’s algorithm
Resource-Allocation Graph Scheme

- **Claim edge** $P_i \rightarrow R_j$ indicated that process $P_j$ may request resource $R_j$; represented by a dashed line.

- Claim edge converts to request edge when a process requests a resource.

- Request edge converted to an assignment edge when the resource is allocated to the process.

- When a resource is released by a process, assignment edge reconverts to a claim edge.

- Resources must be claimed *a priori* in the system.
Resource-Allocation Graph

Diagram showing the allocation of resources to processes. The diagram includes:
- Processes: P1 and P2
- Resources: R1 and R2
- Arrows indicating allocation:
  - P1 → P2
  - P2 → P1
  - R1 → P1
  - R2 → P2

This diagram illustrates the concept of resource allocation in a system, showing how processes P1 and P2 are allocated resources R1 and R2.
Unsafe State In Resource-Allocation Graph

![Diagram showing a resource-allocation graph with processes P₁ and P₂ and resources R₁ and R₂. The graph illustrates an unsafe state with a dashed line indicating a cycle.]
Resource-Allocation Graph Algorithm

- Suppose that process $P_i$ requests a resource $R_j$
- The request can be granted only if converting the request edge to an assignment edge does not result in the formation of a cycle in the resource allocation graph
Banker’s Algorithm

- Multiple instances
- Each process must a priori claim maximum use
- When a process requests a resource it may have to wait
- When a process gets all its resources it must return them in a finite amount of time
Data Structures for the Banker’s Algorithm

Let $n = \text{number of processes}$, and $m = \text{number of resources types}$.

- **Available**: Vector of length $m$. If available $[j] = k$, there are $k$ instances of resource type $R_j$ available.

- **Max**: $n \times m$ matrix. If $\text{Max} [i,j] = k$, then process $P_i$ may request at most $k$ instances of resource type $R_j$.

- **Allocation**: $n \times m$ matrix. If $\text{Allocation}[i,j] = k$, then $P_i$ is currently allocated $k$ instances of $R_j$.

- **Need**: $n \times m$ matrix. If $\text{Need}[i,j] = k$, then $P_i$ may need $k$ more instances of $R_j$ to complete its task.

\[
\text{Need} [i,j] = \text{Max}[i,j] - \text{Allocation} [i,j]
\]
Safety Algorithm

1. Let Work and Finish be vectors of length \( m \) and \( n \), respectively. Initialize:
   
   \[
   \text{Work} = \text{Available} \\
   \text{Finish}[i] = \text{false} \text{ for } i = 0, 1, \ldots, n-1
   \]

2. Find and \( i \) such that both:
   
   (a) \( \text{Finish}[i] = \text{false} \)
   
   (b) \( \text{Need}_i \leq \text{Work} \)

   If no such \( i \) exists, go to step 4

3. \( \text{Work} = \text{Work} + \text{Allocation}_i \)
   
   \( \text{Finish}[i] = \text{true} \)
   
   go to step 2

4. If \( \text{Finish}[i] == \text{true} \) for all \( i \), then the system is in a safe state
Resource-Request Algorithm for Process $P_i$

Request = request vector for process $P_i$. If $Request_i[j] = k$ then process $P_i$ wants $k$ instances of resource type $R_j$

1. If $Request_i \leq Need_i$, go to step 2. Otherwise, raise error condition, since process has exceeded its maximum claim.

2. If $Request_i \leq Available$, go to step 3. Otherwise $P_i$ must wait, since resources are not available.

3. Pretend to allocate requested resources to $P_i$ by modifying the state as follows:

   $$Available = Available - Request;$$
   $$Allocation_i = Allocation_i + Request_i;$$
   $$Need_i = Need_i - Request_i;$$

   - If safe $\Rightarrow$ the resources are allocated to $Pi$
   - If unsafe $\Rightarrow$ $Pi$ must wait, and the old resource-allocation state is restored.
Example of Banker’s Algorithm

- 5 processes $P_0$ through $P_4$;
- 3 resource types:
  - $A$ (10 instances), $B$ (5 instances), and $C$ (7 instances)

Snapshot at time $T_0$:

<table>
<thead>
<tr>
<th>Allocation</th>
<th>Max</th>
<th>Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A$ $B$ $C$</td>
<td>$A$ $B$ $C$</td>
<td>$A$ $B$ $C$</td>
</tr>
<tr>
<td>$P_0$</td>
<td>0 1 0</td>
<td>7 5 3</td>
</tr>
<tr>
<td>$P_1$</td>
<td>2 0 0</td>
<td>3 2 2</td>
</tr>
<tr>
<td>$P_2$</td>
<td>3 0 2</td>
<td>9 0 2</td>
</tr>
<tr>
<td>$P_3$</td>
<td>2 1 1</td>
<td>2 2 2</td>
</tr>
<tr>
<td>$P_4$</td>
<td>0 0 2</td>
<td>4 3 3</td>
</tr>
</tbody>
</table>
Example (Cont.)

- The content of the matrix *Need* is defined to be *Max – Allocation*

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>P₀</em></td>
<td>7</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td><em>P₁</em></td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td><em>P₂</em></td>
<td>6</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td><em>P₃</em></td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td><em>P₄</em></td>
<td>4</td>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

- The system is in a safe state since the sequence < *P₁*, *P₃*, *P₄*, *P₂*, *P₀*> satisfies safety criteria.
**Example: \( P_1 \) Request \((1,0,2)\)**

- Check that Request \( \leq \) Available (that is, \((1,0,2) \leq (3,3,2) \Rightarrow \) true

<table>
<thead>
<tr>
<th>Allocation</th>
<th>Need</th>
<th>Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>A B C</td>
<td>A B C</td>
<td>A B C</td>
</tr>
<tr>
<td>( P_0 )</td>
<td>0 1 0</td>
<td>7 4 3</td>
</tr>
<tr>
<td>( P_1 )</td>
<td>3 0 2</td>
<td>0 2 0</td>
</tr>
<tr>
<td>( P_2 )</td>
<td>3 0 1</td>
<td>6 0 0</td>
</tr>
<tr>
<td>( P_3 )</td>
<td>2 1 1</td>
<td>0 1 1</td>
</tr>
<tr>
<td>( P_4 )</td>
<td>0 0 2</td>
<td>4 3 1</td>
</tr>
</tbody>
</table>

- Executing safety algorithm shows that sequence \(<P_1, P_3, P_4, P_0, P_2>\)
satisfies safety requirement

- Can request for \((3,3,0)\) by \( P_4 \) be granted?

- Can request for \((0,2,0)\) by \( P_0 \) be granted?
Deadlock Detection

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme
Single Instance of Each Resource Type

- Maintain *wait-for* graph
  - Nodes are processes
  - $P_i \rightarrow P_j$ if $P_i$ is waiting for $P_j$

- Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock

- An algorithm to detect a cycle in a graph requires an order of $n^2$ operations, where $n$ is the number of vertices in the graph
Resource-Allocation Graph and Wait-for Graph

Resource-Allocation Graph

Corresponding wait-for graph
Several Instances of a Resource Type

- **Available**: A vector of length \( m \) indicates the number of available resources of each type.

- **Allocation**: An \( n \times m \) matrix defines the number of resources of each type currently allocated to each process.

- **Request**: An \( n \times m \) matrix indicates the current request of each process. If \( \text{Request} [ij] = k \), then process \( P_i \) is requesting \( k \) more instances of resource type \( R_j \).
Detection Algorithm

1. Let Work and Finish be vectors of length $m$ and $n$, respectively. Initialize:
   (a) $Work = Available$
   (b) For $i = 1, 2, \ldots, n$, if $Allocation_i \neq 0$, then $Finish[i] = false$; otherwise, $Finish[i] = true$

2. Find an index $i$ such that both:
   (a) $Finish[i] == false$
   (b) $Request_i \leq Work$

   If no such $i$ exists, go to step 4
Detection Algorithm (Cont.)

3. \[ \text{Work} = \text{Work} + \text{Allocation}_i \]
   \[ \text{Finish}[i] = \text{true} \]
   go to step 2

4. If \( \text{Finish}[i] == \text{false} \), for some \( 1 \leq i \leq n \), then the system is in deadlock state. Moreover, if \( \text{Finish}[i] == \text{false} \), then \( P_i \) is deadlocked

Algorithm requires an order of \( O(m \times n^2) \) operations to detect whether the system is in deadlocked state
Example of Detection Algorithm

- Five processes $P_0$ through $P_4$; three resource types $A$ (7 instances), $B$ (2 instances), and $C$ (6 instances)

- Snapshot at time $T_0$:

<table>
<thead>
<tr>
<th>Allocation</th>
<th>Request</th>
<th>Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A$ $B$ $C$</td>
<td>$A$ $B$ $C$</td>
<td>$A$ $B$ $C$</td>
</tr>
<tr>
<td>$P_0$ 0 1 0</td>
<td>0 0 0</td>
<td>0 0 0</td>
</tr>
<tr>
<td>$P_1$ 2 0 0</td>
<td>2 0 2</td>
<td></td>
</tr>
<tr>
<td>$P_2$ 3 0 3</td>
<td>0 0 0</td>
<td></td>
</tr>
<tr>
<td>$P_3$ 2 1 1</td>
<td>1 0 0</td>
<td></td>
</tr>
<tr>
<td>$P_4$ 0 0 2</td>
<td>0 0 2</td>
<td></td>
</tr>
</tbody>
</table>

- Sequence $<P_0, P_2, P_3, P_1, P_4>$ will result in $Finish[i] = true$ for all $i$
Example (Cont.)

- $P_2$ requests an additional instance of type $C$

<table>
<thead>
<tr>
<th>Request</th>
</tr>
</thead>
<tbody>
<tr>
<td>A B C</td>
</tr>
<tr>
<td>$P_0$ 0 0 0</td>
</tr>
<tr>
<td>$P_1$ 2 0 1</td>
</tr>
<tr>
<td>$P_2$ 0 0 1</td>
</tr>
<tr>
<td>$P_3$ 1 0 0</td>
</tr>
<tr>
<td>$P_4$ 0 0 2</td>
</tr>
</tbody>
</table>

- State of system?
  - Can reclaim resources held by process $P_0$, but insufficient resources to fulfill other processes; requests
  - Deadlock exists, consisting of processes $P_1$, $P_2$, $P_3$, and $P_4$
Detection-Algorithm Usage

- When, and how often, to invoke depends on:
  - How often a deadlock is likely to occur?
  - How many processes will need to be rolled back?
    - one for each disjoint cycle

- If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes “caused” the deadlock.
Recovery from Deadlock: Process Termination

- Abort all deadlocked processes
- Abort one process at a time until the deadlock cycle is eliminated
- In which order should we choose to abort?
  - Priority of the process
  - How long process has computed, and how much longer to completion
  - Resources the process has used
  - Resources process needs to complete
  - How many processes will need to be terminated
  - Is process interactive or batch?
Recovery from Deadlock: Resource Preemption

- Selecting a victim – minimize cost
- Rollback – return to some safe state, restart process for that state
- Starvation – same process may always be picked as victim, include number of rollback in cost factor
End of Chapter 7
